SVXII: R-Z Cluster Model

Simple Cluster Model:

The cluster size, N_{cl}, is generated at random with a **gaussian distribution** with mean, $\langle N_{cl} \rangle$, computed as follows:

$$\langle N_{cl} \rangle = z/p + 1.5,$$

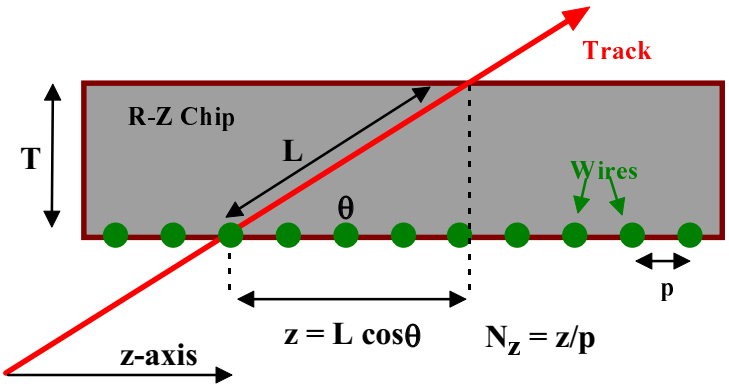
where **z** is the z-component of the track length **L** ($z = L\cos\theta$) and **p is the pitch** (**1/p is the density of wires**). The standard deviation , σ, is given by $\sigma = f_\sigma \sigma_0$, where

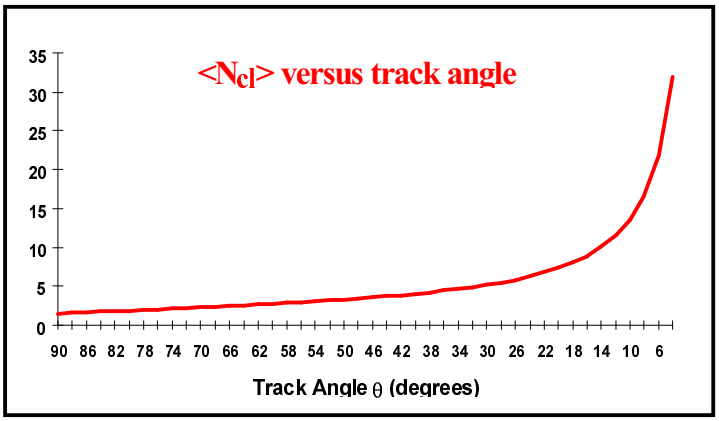
$$\sigma_0 = 0.8.$$

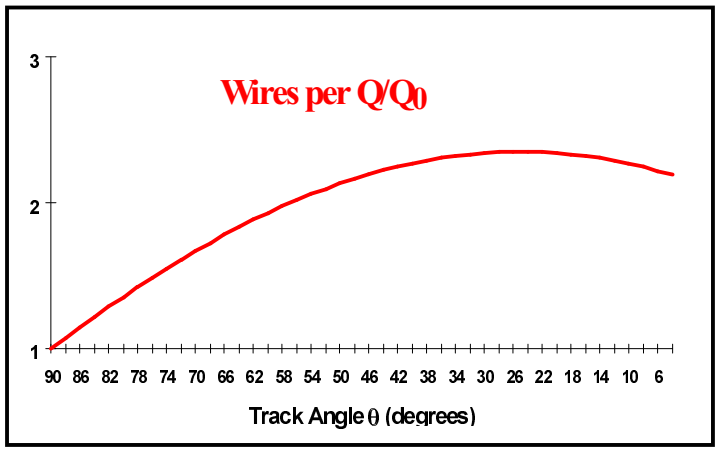
The factor

$$f_\sigma = (z/p+1)Q_0/Q,$$

where **Q** is the amount of charge produced by the track ($Q = \lambda L$) and $Q_0 = \lambda T$ (**1/f is the amount of charge per wire divided by Q_0**).







"Hits" per Track:

The number of "hits" per **t**rack is given by

$$N_{hit} = N_{cl} + NN + N_{over}$$

where **NN = 2** for **nearest neighbor** (**one on each side of the cluster**) and where the **overhead** is

$$N_{over} = 1 \text{ (no noise)}$$

$$N_{over} = 1 + 6 = 7 \text{ (with noise of 2 per chip + NN).}$$

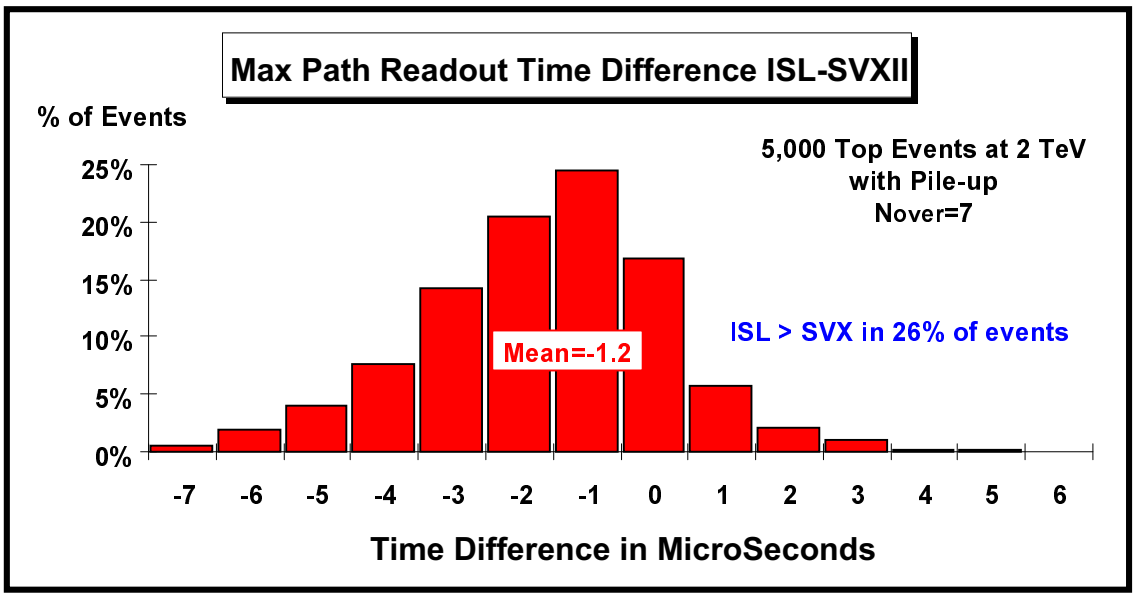
SVXII: Readout Time Comparisons

Maxium Readout Time (event by event) SVXII versus ISL

5,000 Top Events at 2 TeV (<Min-Bias>=3, σ_Z=30 cm):



Comparison with "Super-Naive" Prediction

Last Time: $N_{hit} = 3(1+2+1) = 12$ (old estimate)

Now: $N_{hit} = N_{cl} + NN + 6 + 1$ with $\langle N_{cl}+NN \rangle_{RZ} = 9.5$ $\langle N_{cl}+NN \rangle_{R\phi} = 4.2$

$\langle N_{hit} \rangle_{RZ} = 16.5$ $\langle N_{hit} \rangle_{R\phi} = 11.2$ (new estimate)
